Conditional

Conditional

Pattern matching

Lambdas

let and where

Some functions

For processing conditions, the if-then-else syntax was defined in Haskell98.

if <condition> then <true-value> else <false-value>

if is an expression (which is converted to a value) and not a statement (which is executed) as in many imperative languages. As a consequence, the else is mandatory in Haskell. Since if is an expression, it must evaluate to a result whether the condition is true or false, and the else ensures this.

```
abs :: Int -> Int
abs n = if n >= 0 then n else -n
signum :: Int -> Int
signum n = if n < 0 then -1
           else if n == 0 then 0 else 1
describeLetter :: Char -> String
describeLetter c = if c >= 'a' && c <= 'z'
                   then "Lower case"
                   else if c \ge 'A' \&\& c \le 'Z'
                        then "Upper case"
                        else "Not an ASCII letter"
```

```
addOneIfEven1 :: Integral a => a -> a
addOneIfEven1 n = if even n then n+1 else n
addOneIfEven2 :: Integral a => a -> a
addOneIfEven2 n = n + if even n then 1 else 0
addOneIfEven3 :: Integral a => a -> a
addOneIfEven3 n = (if even n then (+ 1) else (+ 0)) n
addOneIfEven4 :: Integral a => a -> a
addOneIfEven4 n = (if even n then (+ 1) else id) n
```

Remember that

```
isNullLength :: Foldable t => t a -> Bool
isNullLength xs = if length xs == 0 then True else False
is nothing but
isNullLength :: Foldable t => t a -> Bool
isNullLength xs = length xs == 0
or (as we we shall see soon . . . but not really better here!)
isNullLength :: Foldable t => t a -> Bool
isNullLength = (== 0) . length
```

Exercices

The function Data.Char.isSpace returns True for any Unicode space character, and the control characters \t, \n, \r, \f and \v.

```
import Data.Char
```

```
Write hasSpace without if ... then ... else (hint: use (||) :: Bool -> Bool -> Bool).
```

As an alternative to using conditional expressions, functions can also be defined using guarded expressions, in which a sequence of logical expressions called guards is used to choose between a sequence of results of the same type.

- If the first guard is **True**, then the first result is chosen.
- Otherwise, if the second guard is True, then the second result is chosen.
- And so on.

```
signum1 :: Int -> Int
signum1 n = if n < 0 then -1 else
             if n == 0 then 0 else 1
signum2 :: Int -> Int
signum2 n
  | n < 0 = -1
  | n == 0 = 0
  | otherwise = 1
```

```
describeLetter1 :: Char -> String
describeLetter1 c = if c >= 'a' && c <= 'z'
                   then "Lower case"
                   else if c \ge 'A' \&\& c \le 'Z'
                        then "Upper case"
                        else "Not an ASCII letter"
describeLetter2 :: Char -> String
describeLetter2 c
  | c >= 'a' && c <= 'z' = "Lower case"
  | c >= 'A' && c <= 'Z' = "Upper case"
  otherwise
                         = "Not an ASCII letter"
```

```
-- Bad implementation:
fact :: Integer -> Integer
fact n
  | n == 0 = 1
  | n /= 0 = n * fact (n-1)
-- Slightly improved implementation:
fact :: Integer -> Integer
fact n
  | n == 0 = 1
  | otherwise = n * fact (n-1)
```

Exercices

Using guards, define a function

```
max4 :: Int -> Int -> Int -> Int > Int
```

that returns the maximum of four integers.

Conditional

Pattern matching

Lambdas

let and where

Some functions

Many functions have a simple and intuitive definition using pattern matching, in which a sequence of syntactic expressions called patterns is used to choose between a sequence of results of the same type.

The wildcard pattern _ matches any value.

- If the first pattern is matched, then the first result is chosen.
- Otherwise, if the second pattern is matched, then the second result is chosen.
- And so on...

```
-- conditional expression
not :: Bool -> Bool
not b = if b then False else True
-- quarded function
not :: Bool -> Bool
not b
  b = False
  | otherwise = True
-- pattern matching
not :: Bool -> Bool
not False = True
not True = False
```

```
(&&) :: Bool → Bool → Bool
True && True = True
True && False = False
False && True = False
False && False = False
(\&\&) :: Bool -> Bool -> Bool
True && True = True
_ && _ = False
(&&) :: Bool → Bool → Bool
True \&\& b = b
False && _ = False
```

```
guess :: Int -> String
guess 0 = "I am zero"
guess 1 = "I am one"
guess 2 = "I am two"
guess _ = "I am at least three"
-- be careful with the wildcard pattern !
guess :: Int -> String
guess _ = "I am at least three"
guess 0 = "I am zero"
guess 1 = "I am one"
guess 2 = "I am two"
```

Short circuiting

```
(&&)
                               :: Bool -> Bool -> Bool
True && x
                               = x
                               = False
False && _
\lambda > 1 'div' 0
*** Exception: divide by zero
\lambda > f x = x > 0 \&\& x `div` 0 == 0
\lambda > f 1
*** Exception: divide by zero
\lambda > f(-1)
False
```

Short circuiting

```
(||)
                               :: Bool -> Bool -> Bool
True && _
                               = True
    x &&
                                  X
\lambda > 1 'div' 0
*** Exception: divide by zero
\lambda > g x = x > 0 | | x 'div' 0 == 0
\lambda > g 1
True
\lambda > g (-1)
*** Exception: divide by zero
```

A tuple of patterns is itself a pattern, which matches any tuple of the same arity whose components all match the corresponding patterns in order.

Functions fst and snd are defined in the module Data. Tuple:

```
\lambda > :type fst

fst :: (a, b) -> a

\lambda > fst (1,2)

1

\lambda > :type snd

snd :: (a, b) -> b

\lambda > snd (1,2)
```

A tuple of patterns is itself a pattern, which matches any tuple of the same arity whose components all match the corresponding patterns in order.

Functions fst and snd are defined in the module Data. Tuple:

```
fst :: (a, b) -> a
fst (x, _) = x
snd :: (a, b) -> b
snd (_, x) = x
```

A tuple of patterns is itself a pattern, which matches any tuple of the same arity whose components all match the corresponding patterns in order.

```
first3 :: (a, b, c) -> a
first3 (x, _, _) = x
second3 :: (a, b, c) -> b
second3 (_, x, _) = x
third3 :: (a, b, c) -> c
third3 (_, _, x) = x
```

A tuple of patterns is itself a pattern, which matches any tuple of the same arity whose components all match the corresponding patterns in order.

```
first4 :: (a, b, c, d) -> a

first4 (x, _, _, _) = x

second4 :: (a, b, c, d) -> b

second4 (_, x, _, , _) = x

third4 :: (a, b, c, d) -> c

third4 (_, _, x, _) = x

fourth4 :: (a, b, c, d) -> d

fourth4 (_, _, _, x, _) = x
```

Pattern matching – List patterns

A list of patterns is itself a pattern, which matches any list of the same length whose components all match the corresponding patterns in order.

```
-- three characters beginning with the letter 'a'

test :: [Char] -> Bool

test ['a', _, _] = True

test _ = False

-- four characters ending with the letter 'z'

test :: [Char] -> Bool

test [_, _, _, 'z'] = True

test _ = False
```

Pattern matching – List patterns

A list of patterns is itself a pattern, which matches any list of the same length whose components all match the corresponding patterns in order.

These are two different functions

```
-- three characters beginning with the letter 'a'

test :: [Char] -> Bool

test ['a', _, _] = True

test _ = False

-- three characters beginning with the letter 'a'

test :: (Char, Char, Char) -> Bool

test ('a', _, _) = True

test _ = False
```

Exercices

Define a function intersperse' that takes an element and a list and *intersperses* that element between the elements of the list.

The type definition should be

```
intersperse' :: a -> [a] -> [a]

\( \lambda \) intersperse' ',' ""

\( \lambda \) intersperse' ',' "a"

\( \lambda \) intersperse' ',' "abcd"

\( \lambda \) intersperse' "--" ["a", "cd", "edf"]

["a", "--", "cd", "--", "edf"]
```

Exercices

Define the function

```
intercalate' :: [a] -> [[a]] -> [a]
```

The call intercalate' xs xss inserts the list xs in between the lists in xss and concatenates the result.

```
λ > intercalate' "--" []
""
λ > intercalate' "--" ["ab"]
"ab"
λ > intercalate' "--" ["ab", "cde", "fg"]
"ab--cde--fg"
λ > intercalate' ["--"] [["ab"], ["cde"], ["fg"]]
["ab","--","cde","--","fg"]
λ > intersperse' "--" ["ab", "cde", "fg"] -- cf previous exercice
["ab","--","cde","--","fg"]
```

19

Lambdas

Conditional

Pattern matching

Lambdas

let and where

Some functions

Pattern matching – Lambda expression

- An anonymous function is a function without a name.
- It is a Lambda abstraction and might look like this:

```
\xspace x -> x + 1.
```

That backslash is Haskell's way of expressing a λ and is supposed to look like a Lambda . . . if one has enough imagination!

```
\lambda > : type (\x -> x+1)
(\x -> x+1) :: Num a => a -> a
\lambda > (\x -> x+1) 2
```

Pattern matching - Lambda expression

The definition

```
add :: Int -> Int -> Int -> Int add x y z = x + y + z
```

can be understood as meaning

```
add :: Int -> Int -> Int -> Int
add = \x -> (\y -> (\z -> x + y + z))
```

which makes precise that add is a function that takes an integer \mathbf{x} and returns a function which in turn takes another integer \mathbf{y} and returns a function which in turn takes another integer \mathbf{z} and returns the result $\mathbf{x}+\mathbf{y}+\mathbf{z}$.

Pattern matching – Lambda expression

 λ -expressions are useful when defining functions that returns function as results by their very nature, rather than a consequence of currying.

```
const :: a -> b -> a
const x _ = x

-- emphasis const :: a -> (b -> a)
const :: a -> b -> a
const x = \_ -> x
```

Pattern matching - Lambda expression

A closure (the opposite of a combinator) is a function that makes use of free variables in its definition. It closes around some portion of its environment.

```
f :: Num a => a -> a -> a

f x = \y -> x + y
```

f returns a closure, because the variable x, which is bounded outside of the lambda abstraction is used inside its definition.

Exercices

Consider the function

Explain the following session.

```
\lambda > f (+) (*) 2 5
40
\lambda > f (*) (+) 2 5
29
\lambda > let o1 = (+); o2 = (*) in f o1 o2 2 5
40
\lambda > let o = (+) in f o o 2 5
14
\lambda > f (\ x y -> x + 2*y) (\ x y -> x - y) 2 5
-9
```

Exercices

Explain the following functions:

```
g :: Int -> Int
g = \x -> x * x
h :: Int -> Int
h = \x -> g (g x)
i :: Int -> Int
i x = h (h x)
```

Pattern matching – Operator sections

- Functions such as + that are written between their two arguments are called section
- Any operator can be converted into a curried function by enclosing the name of the operator in parentheses, such as
 (+) 1 2.
- More generally, if o is an operator, then expression of the form
 (o), (x o) and (o y) are called sections whose meaning as
 functions can be formalised using λ-expressions as follows:

(o) =
$$\x -> (\y -> x o y)$$

(x o) = $\y -> x o y$
(o y) = $\x -> x o y$

Pattern matching – Operator sections

- (+) is the addition function $\x -> (\y -> x+y)$.
- (1 +) is the successor function \y -> 1+y.
- (1 /) is the reciprocation function \y -> 1/y.
- (* 2) is the doubling function \x -> x*2.
- (/ 2) is the halving function $\x -> x/2$.

Sections

Exercices

Explain the following functions:

```
f :: [Char] -> [Char]
f = ("A" ++)
g :: [Char] -> [Char]
g = (++ "Z")
h :: [Char] -> [Char]
h = \langle x - \rangle f (g x)
i :: [Char] -> [Char]
i = \langle x - \rangle g (f x)
```

Do we have h xs == i xs for every string xs?

let and where

Conditional

Pattern matching

Lambdas

let and where

Some functions

- A where clause is used to divide the more complex logic or calculation into smaller parts, which makes the logic or calculation easy to understand and handle
- A where clause is bound to a surrounding syntactic construct, like the pattern matching line of a function definition.
- A where clause is a syntactic construct

```
bmiTell :: (RealFloat a) => a -> a -> String
bmiTell weight height
  | weight / height ^ 2 <= 18.5 = "Underweight"
  | weight / height ^ 2 < 25.0 = "Healthy weight"
  weight / height ^ 2 < 30.0 = "Overweight"</pre>
  otherwise
                                = "Obese"
bmiTell :: (RealFloat a) => a -> a -> String
bmiTell weight height
  | bmi <= 18.5 = "Underweight"
  | bmi < 25.0 = "Healthy weight"
  | bmi < 30.0 = "Overweight"
  | otherwise = "Obese"
  where
    bmi = weight / height ^ 2
```

```
bmiTell :: (RealFloat a) => a -> a -> String
bmiTell weight height
  | bmi <= underweight = "Underweight"
  | bmi < healthy = "Healthy weight"
  | bmi < overweight = "Overweight"
              = "Obese"
  otherwise
 where
   bmi = weight / height ^ 2
   underweight = 18.5
   healthy = 25
   overweight = 30
```

- A let binding binds variables anywhere and is an expression itself, but its scope is tied to where the let expression appears.
- if a let binding is defined within a guard, its scope is local and it will not be available for another guard.
- A let binding can take global scope overall pattern-matching clauses of a function definition if it is defined at that level.

```
cylinder :: (RealFloat a) => a -> a -> a
cylinder r h =
  let sideArea = 2 * pi * r * h
      topArea = pi * r ^2
  in sideArea + 2*topArea
```

```
λ > let zoot x y z = x*y + z
λ > :type zoot
zoot :: Num a => a -> a -> a -> a
λ > zoot 3 9 2
29
λ > let boot x y z = x*y + z in boot 3 9 2
29
λ > :type boot
<interactive>: error:
    o Variable not in scope: boot
```

```
\lambda > \text{let a = 1; b = 2 in a + b}
3
\lambda > \text{let a = 1; b = a + 2 in a + b}
4
\lambda > \text{let a = 1; a = 2 in a}
<interactive>:: error:
    Conflicting definitions for 'a'
\lambda > \text{let a = 1; b = 2+a; c = 3+a+b in (a, b, c)}
(1,3,7)
```

```
\lambda > let a = 1 in let a = 2; b = 3+a in b 5 \lambda > let a = 1 in let a = a+2 in let b = 3+a in b CInterrupted. \lambda > let f x y = x+y+1 in f 3 5 \lambda > let f x y = x+y; g x = f x (x+1) in g 5 11
```

```
dist :: Floating a \Rightarrow (a, a) \rightarrow (a, a) \rightarrow a
dist (x1,y1) (x2,y2) =
       let xdist = x2 - x1
            ydist = y2 - y1
            sqr z = z*z
       in sqrt ((sqr xdist) + (sqr ydist))
dist :: Floating a \Rightarrow (a, a) \rightarrow (a, a) \rightarrow a
dist (x1,y1) (x2,y2) = sqrt ((sqr xdist) + (sqr ydist))
  where
    xdist = x2 - x1
    ydist = y2 - y1
    sqr z = z*z
```

We can pattern match with let bindings. E.g., we can dismantle a tuple into components and bind the components to names.

```
\lambda > f x y z = let (sx,sy,sz) = (x*x,y*y,z*z) in (sx,sy,sz)

\lambda > f 1 2 3

(1,4,9)

\lambda > g x y = let (sx,_) = (x*x,y*y) in sx

\lambda > g 2 3

4

\lambda > h x = let ((sx,cx),qx) = ((x*x,x*x*x),x*x*x*x) in (sx,cx,qx)

\lambda > h 2

(4,8,16)
```

let bindings are expressions.

```
\lambda > 1 + \text{let } x = 2 \text{ in } x*x

5

\lambda > (\text{let } x = 2 \text{ in } x*x) + 1

5

\lambda > (\text{let } (x,y,z) = (1,2,3) \text{ in } x+y+z) * 100

600

\lambda > (\text{let } x = 2 \text{ in } (+ x)) 3

5

\lambda > \text{let } x=3 \text{ in } x*x + \text{let } x=4 \text{ in } x*x

25
```

Some functions

Conditional

Pattern matching

Lambdas

let and where

Some functions

```
dblFact2 :: Int -> Int
dblFact2 n = go n
 where
   go 0 = 1
   go m
      | p m = m * go (m-1)
      | otherwise = go (m-1)
     where
       nParity2 = n \mod 2
       p m = m \mod 2 == nParity2
```

```
dblFact3 :: Int -> Int
dblFact3 0 = 1
dblFact3 1 = 1
dblFact3 n = n * dblFact3 (n-2)
```

```
dblFact4 :: Int -> Int
dblFact4 n = product [n,n-2..1]
```

Collatz conjecture

The Collatz conjecture is one of the most famous unsolved problems in mathematics. It concerns sequences of integers in which each term is obtained from the previous term as follows:

$$u_n = \begin{cases} u_{n-1}/2 & \text{if } u_{n-1} \text{ is even} \\ 3u_{n-1} + 1 & \text{if } u_{n-1} \text{ is odd} \end{cases}$$

For instance, starting with n=19, one gets the sequence 19,58,29,88,44,22,11,34,17,52,26,13,40,20,10,5,16,8,4,2,1.

Collatz conjecture

The Collatz conjecture is one of the most famous unsolved problems in mathematics. It concerns sequences of integers in which each term is obtained from the previous term as follows:

$$u_n = \begin{cases} u_{n-1}/2 & \text{if } u_{n-1} \text{ is even} \\ 3u_{n-1} + 1 & \text{if } u_{n-1} \text{ is odd} \end{cases}$$

For instance, starting with n=19, one gets the sequence 19,58,29,88,44,22,11,34,17,52,26,13,40,20,10,5,16,8,4,2,1.

Ackermann-Péter function

$$A(0, n) = n + 1$$

 $A(m+1, 0) = A(m, 1)$
 $A(m+1, n+1) = A(m, A(m+1, n))$

```
aP :: (Num \ a, Eq \ a, Num \ b, Eq \ b) => a -> b -> b
aP \ 0 \ n = n+1
aP \ m \ 0 = aP \ (m-1) \ 1
aP \ m \ n = aP \ (m-1) \ (aP \ m \ (n-1))
```

Prime numbers

A prime number (or a prime) is a natural number greater than 1 that is not a product of two smaller natural numbers.

```
-- very naive

isPrime :: Integral a => a -> Bool

isPrime 0 = False

isPrime 1 = False

isPrime n = go 2

where

go k

| k >= n = True

| otherwise = n `mod` k /= 0 && go (k+1)
```

Ping-pong programming

```
-- odd number predicate
isOdd :: (Eq a, Num a) => a -> Bool
isOdd 0 = False
isOdd\ 1 = True
isOdd n = isEven (n-1)
-- even number predicate
isEven :: (Eq a, Num a) => a -> Bool
isEven 0 = True
isEven 1 = False
isEven n = isOdd (n-1)
```

Factorial

Factorial

```
fact3 :: (Ord a, Num a) => a -> a
fact3 = go 1
  where
    go m n
      \mid m > n = 1
      \mid otherwise = m * go (m+1) n
fact4 :: (Eq t, Num t) \Rightarrow t \rightarrow t
fact4 n = go 1 n
  where
    go acc 0 = acc
    go acc m = go (acc*m) (m-1)
```

Factorial

```
fact5 :: (Enum a, Num a) => a -> a
fact5 n = product [1..n]
```

Pascal's relation

$$\binom{n+1}{k+1} = \binom{n}{k} + \binom{n}{k+1}$$

Recursion

Exercices

Consider the following functions:

```
fix :: (a -> a) -> a
fix f = f (fix f)

fact :: Integer -> Integer
fact = fix (\ r n -> if n == 0 then 1 else n * r (n-1))

Explain:
    \( \lambda \) fact 5
120
```
